(Communicated by Iwan Duursma)

Abstract. We consider the problem of constructing optimal authentication codes with splitting. New infinite families of such codes are obtained. In particular, we establish the first known infinite family of optimal authentication codes with splitting that are secure against spoofing attacks of order two.

1. Introduction. In the standard model of authentication theory [13, 14, 15, 18], a transmitter wants to send some information to a receiver across an insecure channel while an opponent with access to the channel wants to deceive the receiver. The opponent can either insert new messages into the channel, or intercept messages from the transmitter and modify them into his own. In each case, the opponent’s goal is to deceive the receiver into believing that the new messages are authentic (coming from the transmitter). The first attack based on insertion of new messages is known as impersonation and the second attack based on modification of messages from the transmitter is known as substitution.

More formally, let S denote the set of all source states, M be the set of all messages, and E be the set of all encoding rules. All these are finite sets. A source state is the information the transmitter wishes to communicate to the receiver. An encoding rule is an injection from S to \(2^M\). The transmitter and receiver agree beforehand on a secret encoding rule \(e \in E\). To communicate a source state \(s \in S\), the transmitter determines \(M = e(s)\) (note that \(M \subseteq M\)) and chooses a message \(m \in M\) to send to the receiver. The receiver accepts the received message as authentic if there exists an \(M\) in the image of \(e\) containing the received message.

For the receiver to recover the source state, each encoding rule must satisfy the condition
\[ e(s) \cap e(s') = \emptyset, \quad \text{for distinct } s, s' \in S. \]

The triple \((S, M, E)\) is called an \textit{authentication code}, or \textit{A-code} in short.

An A-code \((S, M, E)\) can be represented by an \(|E| \times |S|\) matrix, whose rows are indexed by authentication rules, and columns indexed by source states, such that the entry in row \(e \in E\) and column \(s \in S\) is \(e(s)\).

For \(k\) an integer and \(X\) a finite set, we denote by \(X^k\) the set of all \(k\)-subsets of \(X\). Research on authentication codes have focused on the case when every encoding rule is an injection from \(S\) to \((M^c)\), for some positive \(c\). Such an A-code is called a \textit{c-splitting A-code}. A 1-splitting A-code is also known as an \textit{A-code without splitting}, and a \(c\)-splitting A-code with \(c \geq 2\) is known as an \textit{A-code with splitting}. A-codes with splitting are useful for the analysis of authentication with arbitration [9], an extended model of authentication introduced by Simmons [16, 17] for the scenario when the transmitter and receiver may both be deceptive.

In a \textit{spoofing attack of order i} [10], the opponent observes \(i\) distinct messages sent by the transmitter through the insecure channel under the same encoding rule. The opponent then inserts a new message (distinct from the \(i\) messages already sent), hoping to have it accepted by the receiver as authentic. Within this framework, impersonation and substitution attacks are just spoofing attacks of order zero and one, respectively. While these attacks have been rather well studied for A-codes, less is known for the case of spoofing attacks of order \(i \geq 2\), especially on \(c\)-splitting A-codes when \(c \geq 2\).

The probability distribution on the set of source states \(S\) induces a probability distribution on \(S^i\), \(i \geq 0\). Given these probability distributions, the transmitter and receiver choose a probability distribution on \(E\), called an \textit{encoding strategy}. For any \(s \in S\) and \(e \in E\), the transmitter also chooses a probability distribution on \(e(s)\), called a \textit{splitting strategy}. The opponent is assumed to know the encoding and splitting strategies. The transmitter and receiver chooses the encoding and splitting strategies to minimize the probability of being deceived by the opponent. We denote by \(P_{d_i}\) the probability that the opponent can deceive the receiver with a spoofing attack of order \(i\). The following lower bound on \(P_{d_i}\) is known.

**Proposition 1.1** (Huber [7]). \textit{In a c-splitting A-code} \((S, M, E)\),
\[ P_{d_i} \geq c \cdot \frac{|S| - i}{|M| - i}, \]
for every \(i \geq 0\).

A \(c\)-splitting A-code is said to be \((t - 1)\)-fold secure against spoofing if \(P_{d_i} = c(|S| - i)/(|M| - i)\), for all \(i, 0 \leq i < t\). For succinctness, we call such a code a \((t, c)\)-splitting A-code.

Huber [7] also showed that the number of encoding rules must be large enough if an A-code is to be \((t - 1)\)-fold secure against spoofing.

**Proposition 1.2** (Huber [7]). \textit{In a} \((t, c)\)-splitting A-code \((S, M, E)\),
\[ |E| \geq \frac{1}{c^t} \cdot \frac{\binom{|M|}{t}}{\binom{|S|}{t}}. \]
For efficiency, we want the number of encoding rules in an A-code to be as small as possible. We call a \((t, c)\)-splitting A-code *optimal* if the lower bound in Proposition 1.2 is met with equality.

The main contribution of this paper is on the construction of optimal \((t, c)\)-splitting A-codes with three source states, for \(c \geq 2\) and \(t \in \{2, 3\}\). In particular, we show that the following two new families of A-codes exist:

(i) \((2, 5)\)-splitting A-codes with three source states and \(v\) messages, for all \(v \equiv 1 \mod 150, v \neq 301\).

(ii) \((3, 2)\)-splitting A-codes with three source states and \(v\) messages, for all \(v \equiv 2 \mod 8\).

The \((3, 2)\)-splitting A-codes we obtained is the first known infinite family of \((t, c)\)-splitting A-codes with \(t > 2\) and \(c > 1\). We also prove that a \((2, c)\)-splitting A-code with \(k\) source states and \(v\) messages exists for all sufficiently large \(v\) (with \(k\) and \(c\) fixed).

2. Preliminaries. This section serves to provide notions and results that are required for our construction in subsequent sections.

The ring \(\mathbb{Z}/n\mathbb{Z}\) is denoted \(\mathbb{Z}_n\).

2.1. Design-Theoretic Background. Huber [7] defined splitting \(t\)-designs, generalizing the splitting 2-designs of Ogata et al. [12].

**Definition 2.1.** Let \(t, v, k, c, \lambda\) be positive integers, with \(t \leq k\) and \(ck \leq v\). A splitting \(t\)-design, or more precisely, a splitting \(t\)-\((v, k \times c, \lambda)\) design, is a pair \((X, A)\) such that

(i) \(X\) is a set of \(v\) elements, called points;

(ii) \(A\) is a set of \(k \times c\) arrays, called blocks, with entries from \(X\), such that each point of \(X\) occurs at most once in each block;

(iii) for every \(\{x_i : 1 \leq i \leq t\} \in \binom{X}{t}\), there are exactly \(\lambda\) blocks in which \(x_i, 1 \leq i \leq t\), occur in \(t\) different rows.

Note that a splitting \(t\)-(\(v, k \times 1, \lambda)\) design coincides with the classical notion of a \(t\)-(\(v, k, \lambda)\) design. Huber [7] proved the equivalence between splitting \(t\)-designs and optimal splitting A-codes.

**Theorem 2.2** (Huber [7]). There exists a splitting \(t\)-(\(v, k \times c, 1\) design if and only if there exists an optimal \((t, c)\)-splitting A-code for \(k\) equiprobable source states, having \(v\) messages and \(\binom{v}{t}/c^{t(\binom{t}{c})}\) encoding rules.

The necessary divisibility conditions for the existence of splitting \(t\)-designs are as follows.

**Proposition 2.1** (Huber [7]). The necessary conditions for the existence of a splitting \(t\)-(\(v, k \times c, \lambda)\) design are

\[
\lambda \binom{v-s}{t-s} \equiv 0 \mod c^{t-s} \binom{k-s}{t-s}, \text{ for all } s, 0 \leq s \leq t.
\]

Sometimes, the points of a splitting \(t\)-design \((X, A)\) can be identified with the elements of an additive group \(\Gamma\), so that \(X = \Gamma\). If the set of blocks \(A\) can be generated by a set \(\mathcal{B} \subseteq \mathcal{A}\), that is,

\[
\mathcal{A} = \bigcup_{B \in \mathcal{B}} \{B + g : g \in \Gamma\},
\]

then \(\mathcal{B}\) is called a set of base blocks of \((X, A)\).
Example 2.1. Let \( X = \mathbb{Z}_{151} \). The set containing the single array
\[
A = \begin{pmatrix}
0 & 1 & 2 & 3 & 4 \\
5 & 13 & 59 & 105 & 118 \\
28 & 67 & 73 & 112 & 134
\end{pmatrix}
\]
as a base block, generates the set of blocks \( \mathcal{A} \) for a splitting \( 2-(151, 3 \times 5, 1) \) design \( (X, \mathcal{A}) \).

Our constructions for splitting \( t \)-designs also rely on group divisible designs (GDD). Let \( t, k, \) and \( v \) be nonnegative integers. A group divisible \( t \)-design of order \( v \) and block size \( k \), denoted \( \text{GDD}(t, k, v) \), is a triple \((X, \mathcal{G}, \mathcal{A})\) satisfying the following properties:

(i) \( X \) is a set of \( v \) elements, called points;
(ii) \( \mathcal{G} = \{G_1, \ldots, G_n\} \) is a partition of \( X \) into subsets, called groups;
(iii) \( \mathcal{A} \subseteq \binom{X}{k} \), whose elements are called blocks, such that each \( A \in \mathcal{A} \) intersects any group \( G \in \mathcal{G} \) in at most one point;
(iv) every \( T \in \binom{X}{t} \) containing at most one point from each group is contained in exactly one block.

The type of a \( \text{GDD}(t, k, v) \) \((X, \mathcal{G}, \mathcal{A})\) is the multiset \([\{G : G \in \mathcal{G}\}] \). We use the exponential notation to describe the type of a GDD: a GDD of type \( g_1^n \cdots g_s^n \) is a GDD where there are exactly \( n_i \) groups of size \( g_i \), \( 1 \leq i \leq s \).

We require the following result.

Theorem 2.3 (Hanani [4], Brouwer et al. [1], Mills [11], Ji [8]).

(i) There exists a \( \text{GDD}(2,3, gn) \) of type \( g^n \) if and only if \( n \geq 3, (n - 1)g \equiv 0 \mod 2, \) and \( n(n - 1)g^2 \equiv 0 \mod 6 \).
(ii) There exists a \( \text{GDD}(2,4, gn) \) of type \( g^n \) if and only if \( n \geq 4, (n - 1)g \equiv 0 \mod 3, \) and \( n(n - 1)g^2 \equiv 0 \mod 12 \), with the exception of \((g,n) \in \{(2,4), (6,4)\}\).
(iii) For \( n > 3, n \neq 5 \), a \( \text{GDD}(3,4, gn) \) of type \( g^n \) exists if and only if \( gn \equiv 0 \mod 2 \) and \( n(n - 1)(n - 2)g \equiv 0 \mod 3 \). A \( \text{GDD}(3,4, 5g) \) of type \( g^5 \) exists when \( g \equiv 0 \mod 2, g \neq 2, \) and \( g \neq 10, 26 \mod 48 \).

Analogous to splitting \( t \)-designs, a “splitting” version of a GDD can be defined.

This has been done by Wang [19] for \( t = 2 \). Here, we extend it to general \( t \).

A splitting group divisible \( t \)-design, denoted splitting \( \text{GDD}(t, k \times c, v) \), is a triple \((X, \mathcal{G}, \mathcal{A})\) satisfying the following properties:

(i) \( X \) is a set of \( v \) elements, called points;
(ii) \( \mathcal{G} = \{G_1, \ldots, G_n\} \) is a partition of \( X \) into subsets, called groups;
(iii) \( \mathcal{A} \) is a set of \( k \times c \) arrays, called blocks, with entries from \( X \), such that each point of \( X \) occurs at most once in each block;
(iv) for every \( \{x_i : 1 \leq i \leq t\} \in \binom{X}{t} \) containing at most one point from each group, there is exactly one block in which \( x_i, 1 \leq i \leq t \), occur in \( t \) different rows.

The type of a splitting GDD is defined in a fashion similar to that for a GDD.

Splitting GDDs play an important role in the recursive constructions of splitting designs. The following is a straightforward extension of Wilson’s Fundamental Construction for GDDs [21, 22] to splitting GDDs.

Theorem 2.4 (Fundamental Construction). Let \((X, \mathcal{G}, \mathcal{A})\) be a \( \text{GDD}(t, k, v) \). Suppose that for each block \( A \in \mathcal{A} \), there exists a splitting \( \text{GDD}(t, k' \times c, kc) \) of type \( c^c \).
\((X_A, S_A, B_A)\), where
\[
X_A = A \times \{1, \ldots, c\},
\]
\[
S_A = \{\{x\} \times \{1, \ldots, c\} : x \in A\},
\]
then there exists a splitting \(GDD(t, k' \times c, vc)\) of type \([c|G| : G \in S] (X', S', A')\), where
\[
X' = X \times \{1, \ldots, c\},
\]
\[
S' = \{G \times \{1, \ldots, c\} : G \in S\},
\]
\[
A' = \cup_{A \in A} B_A.
\]

Since the trivial splitting \(GDD(t, k, vc)\) of type \(c^k\) (containing only one block) always exists for any \(t, k,\) and \(c\), we have the following.

Corollary 2.1. If there exists a \(GDD(t, k, v)\) of type \(g_1^{n_1} \cdots g_s^{n_s}\), then there exists a splitting \(GDD(t, k \times c, vc)\) of type \((cg_1)^{n_1} \cdots (cg_s)^{n_s}\).

As shown by Ge et al. [3], we can also fill in the groups of a splitting \(GDD\) with a splitting 2-design to obtain new splitting 2-designs.

Proposition 2.2 (Filling-In Groups). Let \((X, S, A)\) be a splitting \(GDD(2, k \times c, v)\). If for each \(G \in S\), there exists a splitting 2-design of order \(\lambda(v + 1, k \times c, v_1)\), then there exists a splitting 2-design of order \(\lambda(v + 1, k \times c, v_1)\) design.

2.2. State of Affairs. The following theorem summarizes the state of knowledge on the existence of splitting \(t\)-designs with \(\lambda = 1\).

Theorem 2.5 (Du [2], Ge et al. [3], Wang [19], Wang and Su [20]). The necessary divisibility conditions (of Proposition 2.1) are also sufficient for the existence of a splitting 2-design when
(i) \((k, c) = (2, 2n)\), for any positive integer \(n\);
(ii) \((k, c) = (2, 3)\), except for \(v = 10\);
(iii) \((k, c) = (3, 2)\), except for \(v = 9\);
(iv) \((k, c) = (3, 3)\), with the possible exception of \(v = 55\);
(v) \((k, c) = (4, 2)\), with the possible exception of \(v \in \{49, 385\}\).

In addition, there exists a 2-design \((v, 3 \times 4, 1)\) design for all \(v \equiv 1 \mod 96\).

3. Nonexistence and Asymptotic Existence. Let \(\lambda\) be a positive integer. The complete (loopless) multigraph on \(v\) vertices, denoted \(\lambda K_v\), is the graph where every pair of distinct vertices is connected by \(\lambda\) edges. Let \(G\) be a simple graph without isolated vertices. A \(G\)-design of order \(v\) and index \(\lambda\) is a partition of edge set of \(\lambda K_v\) into subgraphs, each of which is isomorphic to \(G\). If \(e(G)\) denotes the number of edges in \(G\), and \(d(G)\) denotes the greatest common divisor of the degrees of vertices in \(G\), then simple counting shows that the conditions
(i) \(\lambda(v - 1) \equiv 0 \mod 2e(G)\), and
(ii) \(\lambda(v - 1) \equiv 0 \mod d(G)\)
are necessary for the existence of a \(G\)-design of order \(v\) and index \(\lambda\). A celebrated result of Wilson [23] states that these necessary conditions are also asymptotically sufficient.
**Theorem 3.1** (Wilson [23]). Let $G$ be a simple graph without isolated vertices. Then there exists a constant $v_0$ depending only on $G$ and $\lambda$ such that a $G$-design of order $v$ and index $\lambda$ exist for all $v \geq v_0$ satisfying $\lambda v(v-1) \equiv 0 \mod 2e(G)$ and $\lambda(v-1) \equiv 0 \mod d(G)$.

Let $K_{k \times c}$ denote the complete $k$-partite graph, with each part having $c$ vertices. A splitting 2-$(v,k \times c, \lambda)$ design $(X, A)$ is equivalent to a $K_{k \times c}$-design of order $v$ and index $\lambda$ through the following correspondence:

(i) a point in $X$ corresponds to a vertex in $\lambda K_v$,

(ii) a block $A \in A$ corresponds to the complete $k$-partite graph, where the $i$-th part contains $c$ vertices corresponding to the $c$ entries in row $i$ of $A$, $1 \leq i \leq k$.

Applying Theorem 3.1 with $G = K_{k \times c}$ then gives the following result on the asymptotic existence of splitting 2-designs.

**Corollary 3.1.** There exists a constant $v_0$ depending only on $k$, $c$, and $\lambda$, such that a splitting 2-$(v,k \times c, \lambda)$ design exists for all $v \geq v_0$ satisfying $\lambda v(v-1) \equiv 0 \mod c^2k(k-1)$ and $\lambda(v-1) \equiv 0 \mod c(k-1)$.

We end this section with a nonexistence result. Huang [6] has shown that the number of complete $k$-partite graphs required to partition the edge set of $K_v$ is at least $[(v-1)/(k-1)]$. This has the following consequence.

**Proposition 3.1.** There does not exist a splitting 2-$(k(k-1)c^2+1,k \times c,1)$ design, for all $k,c \geq 2$.

**Proof.** Suppose a splitting 2-$(k(k-1)c^2+1,k \times c,1)$ design exists. The number of blocks in this splitting 2-design is $(k(k-1)c^2+1)/k$. This would mean that we can partition the edge set of $K_{(k-1)c^2+1}$ into $(k(k-1)c^2+1)/k$ complete $k$-partite subgraphs. This is impossible by Huang’s result, since $[(k(k-1)c^2/(k-1))] = c^2 > (k(k-1)c^2+1)/k$.

The definite exceptions in Theorem 2.5 are special cases of Proposition 3.1.

4. **Splitting 2-Designs.** In this section, we establish the existence of an infinite family of splitting 2-$(v,3 \times 5,1)$ designs, and remove $v = 385$ as a possible exception from Theorem 2.5(v).

**Proposition 4.1.** There exists a splitting 2-$(v,3 \times 5,1)$ design for all $v \equiv 1 \mod 150$, except possibly when $v = 301$.

**Proof.** A splitting 2-$(151,3 \times 5,1)$ design is exhibited in Example 2.1, so let $v \geq 451$. Write $v = 150m+1$, for some integer $m \geq 3$. A GDD(2, {3}, $30m$) of type $30m$ exists by Theorem 2.3(i). Apply Corollary 2.1 to obtain a splitting GDD(2, 3 × 5, 150m) of type 150$m$. Now fill in the groups of this splitting GDD with a splitting 2-$(151,3 \times 5,1)$ design (which has been constructed in Example 2.1) to obtain a splitting 2-$(150k+1,3 \times 5,1)$ design.

**Proposition 4.2.** There exists a splitting 2-$(385,4 \times 2,1)$ design.

**Proof.** A GDD(2, {4}, 192) of type 48 exists by Theorem 2.3(ii). Apply Corollary 2.1 to obtain a splitting GDD(2, 4 × 2, 384) of type 96. Now fill in the groups of this splitting GDD with a splitting 2-$(97,4 \times 2,1)$ design (which exists by Theorem 2.5) to obtain a splitting 2-$(385,4 \times 2,1)$ design.
5. Splitting 3-Designs. In this section, we establish the existence of the first known infinite family of splitting 3-designs with $c > 1$.

Let $t$, $k$, and $v$ be nonnegative integers. A $(t, k)$ candelabra system of order $v$ is a quadruple $(X, S, \mathcal{G}, A)$ that satisfies the following properties:

(i) $X$ is a set of $v$ elements, called points;
(ii) $S \subseteq X$, called the stem;
(iii) $S = \{G_1, \ldots, G_m\}$ is a partition of $X \setminus S$ (elements of $\mathcal{G}$ are called groups);
(iv) $A \subseteq \binom{X}{k}$, whose elements are called blocks;
(v) every $T \in \binom{X}{k}$ with $|T \cap (S \cup G_i)| < t$ for all $i$, is contained in a block in $A$.

The type of a $(t, k)$ candelabra system $(X, S, \mathcal{G}, A)$ is the multiset $|G| : G \in \mathcal{G}$.

A $(t, k)$ candelabra system of type $g_1^{n_1} \cdots g_r^{n_r}$ with a stem of size $s$ is denoted $(t, k)$-CS($g_1^{n_1} \cdots g_r^{n_r} : s$).

Here, we introduce the notion of splitting candelabra systems.

A splitting $(t, k \times c)$ candelabra system of order $v$ is a quadruple $(X, S, \mathcal{G}, A)$ that satisfies the following properties:

(i) $X$ is a set of $v$ elements, called points;
(ii) $S \subseteq X$, called the stem;
(iii) $S = \{G_1, \ldots, G_m\}$ is a partition of $X \setminus S$ (elements of $\mathcal{G}$ are called groups);
(iv) $A$ is a set of $k \times c$ arrays, called blocks, with entries from $X$, such that each point of $X$ occurs at most once in each block;
(v) for every $\{x_i : 1 \leq i \leq t\} \in \binom{X}{t}$ with $|T \cap (S \cup G_i)| < t$ for all $i$, there is exactly one block in which $x_i$, $1 \leq i \leq t$, occur in $t$ different rows.

We use the same notation for splitting $(t, k)$ candelabra systems as those for $(t, k)$ candelabra systems.

The following theorem is an extension of Hartman’s Fundamental Construction [5] from $(3, k)$ candelabra systems to splitting $(3, k)$ candelabra systems.

**Theorem 5.1.** If there exist a $(3, k)$-CS($g_1^{n_1} \cdots g_r^{n_r} : s$), a splitting $(3, k' \times c)$-CS($m^{k-1} : a$), and a splitting GDD$(3, k' \times c, mk)$ of type $m^k$, then there exists a splitting $(3, k' \times c)$-CS($g_1^{n_1} \cdots g_r^{n_r} : m(s-1) + a$).

**Proof.** Let $(X, S, \mathcal{G}, A)$ be a $(3, k)$-CS($g_1^{n_1} \cdots g_r^{n_r} : s$), and let $\infty$ be a distinguished point in $S$. For $Y \subseteq X$, define the set of points

$$P(Y) = ((Y \setminus \{\infty\}) \times \mathbb{Z}_m) \cup (\{\infty\} \times \mathbb{Z}_a).$$

Further define

$$S' = ((S \setminus \{\infty\}) \times \mathbb{Z}_m) \cup (\{\infty\} \times \mathbb{Z}_a),$$

$$\mathcal{G}' = \{G \times \mathbb{Z}_m : G \in \mathcal{G}\}.$$

For each $A \in \mathcal{A}$ containing the point $\infty$, let

$$(P(A), \{\infty\} \times \mathbb{Z}_a, \{x\} \times \mathbb{Z}_m : x \in A \setminus \{\infty\}, B_A)$$

be a splitting $(3, k' \times c)$-CS($m^{k-1} : a$), and for each $A \in \mathcal{A}$ not containing the point $\infty$, let

$$(A \times \mathbb{Z}_m, \{x\} \times \mathbb{Z}_m : x \in A, \mathcal{E}_A)$$

be a splitting GDD$(3, k' \times c, 3m)$ of type $m^k$.

It is easy to check that $(P(X), S', \mathcal{G}', \mathcal{A}')$, where

$$\mathcal{A}' = \left( \bigcup_{A \in \mathcal{A} : \infty \in A} B_A \right) \cup \left( \bigcup_{A \in \mathcal{A} : \infty \notin A} \mathcal{E}_A \right),$$

is an $(t, k \times c)$-CS($g_1^{n_1} \cdots g_r^{n_r} : s$).
is the required splitting \((3, k' \times c) \text{-CS}((g_1 m)^{n_1} \cdots (g_r m)^{n_r} : m(s - 1) + a)\). □

We can also fill in the groups of a splitting candelabra system by splitting 3-designs to obtain larger splitting 3-designs.

**Proposition 5.1.** If there exists a splitting \((3, k \times c) - \text{CS}(g_1^{n_1} \cdots g_r^{n_r} : s)\), where \(s \leq 2\), and there exists a splitting \(3-(g_i + s, k \times c, 1)\) design for each \(i, 1 \leq i \leq r\), then there exists a splitting \(3-(s + \sum_{i=1}^r g_i n_i, k \times c, 1)\) design.

**Proof.** Let \((X, S, G, A)\) be a splitting \((3, k \times c) - \text{CS}(g_1^{n_1} \cdots g_r^{n_r} : s)\), where \(s \leq 2\). For each \(G \in S\), let \((G \cup S, B_G)\) be a splitting \(3-([G] + s, k \times c, 1)\) design. Then \((X, A \cup (\cup_{G \in S} B_G))\) is the required splitting \(3-(s + \sum_{i=1}^r g_i n_i, k \times c, 1)\) design. □

To apply Theorem 5.1 and Proposition 5.1, we require some splitting candelabra systems to start with.

**Lemma 5.2.** There exist a splitting \((3, 3 \times 2) - \text{CS}(8^2 : 0)\) and a splitting \((3, 3 \times 2) - \text{CS}(8^2 : 2)\).

**Proof.** Let \(X = \mathbb{Z}_{16}\) and \(G = \{\{2i + j : 0 \leq i \leq 7\} : j \in \{0, 1\}\}\). Let

\[
\mathcal{B} = \left\{ \begin{pmatrix} 0 & 4 \\ 6 & 9 \\ 7 & 11 \end{pmatrix}, \begin{pmatrix} 0 & 14 \\ 8 & 10 \\ 13 & 15 \end{pmatrix}, \begin{pmatrix} 0 & 2 \\ 4 & 1 \\ 7 & 15 \end{pmatrix}, \begin{pmatrix} 0 & 13 \\ 1 & 9 \\ 14 & 6 \end{pmatrix}, \begin{pmatrix} 0 & 6 \\ 9 & 7 \\ 12 & 10 \end{pmatrix} \right\}.
\]

Then \((X, G, \emptyset, A)\), where \(A = \cup_{B \in \mathcal{B}} \{B + 2i \mod 16 : 0 \leq i < 8\}\), is a splitting \((3, 3 \times 2) - \text{CS}(8^2 : 0)\).

Now let \(S = \{x, y\}\) be such that \(S \cap X = \emptyset\), and let

\[
\mathcal{E} = \left\{ \begin{pmatrix} x & y \\ 2i & 2i + 2 \\ 2j + 1 & 2j + 3 \end{pmatrix} : i, j \in \{0, 2, 4, 6\} \right\}.
\]

Then \((X \cup \{x, y\}, S, G, A \cup \mathcal{E})\) is a splitting \((3, 3 \times 2) - \text{CS}(8^2 : 2)\). □

We now establish an infinite family of splitting 3-designs.

**Theorem 5.3.** A splitting \(3-(v, 3 \times 2, 1)\) design exists if and only if \(v \equiv 2 \mod 8\).

**Proof.** Necessity of the condition \(v \equiv 2 \mod 8\) follows from Proposition 2.1.

Huber [7] has shown the existence of a splitting \(3-(10, 3 \times 2, 1)\) design, so we consider \(v > 10\). Write \(v = 8m + 2\), for some \(m \geq 2\). Let \(X\) be a set of \(m + 1\) points, containing \(\infty\) as a distinguished point. It is easy to verify that \((X, \{\infty\}, \{\{x\} : x \in X \setminus \{\infty\}\}, \{\infty\})\) is a \((3, 3) - \text{CS}(1^m : 1)\). Apply Theorem 5.1 with a splitting \((3, 3 \times 2) - \text{CS}(8^2 : 2)\) (which exists by Lemma 5.2) and a splitting \(\text{GDD}(3, 3 \times 2, 24)\) of type \(8^3\) (whose existence is implied by the trivial \(\text{GDD}(3, 3, 12)\) of type \(4^3\) and Corollary 2.1) to obtain a splitting \((3, 3 \times 2) - \text{CS}(8^m : 2)\). Now apply Proposition 5.1 to this splitting \((3, 3 \times 2) - \text{CS}(8^m : 2)\) with a splitting \(3-(10, 3 \times 2, 1)\) design to obtain a splitting \((3-(8m + 2, 3 \times 2, 1)\) design. □

6. **Conclusion.** Determining the existence of optimal \(c\)-splitting authentication codes with \(k\) source states that are \((t - 1)\)-fold secure against spoofing is a difficult problem, when \(k, c\) and \(t\) are large. New constructions, both direct and recursive, need to be developed in order to make further progress on the problem.
Acknowledgment. The authors would like to thank Gennian Ge and Alan Ling for helpful discussions.
